Neither relevant for current talk

Diagnostic Complexities in Current Clinical and Morphological Criteria for Alzheimer's Disease

- Spectrum of pathologies accumulate in the aging brain

- Neural reserve – diverse pathologies decrease reserve

- Complex mix of pathologies expands beyond cerebral infarcts and LB
  - Vascular – vessel disease
  - Degenerative – TDP and HS
  - Primary Age Related Tauopathy
  - Complex Mix of Genetic factors (eg. apoE and TMEM106)

- Overlap of clinical phenotypes
  - Episodic memory - primary domain of AD pathology, TDP-43 pathology, primary age related tauopathy
  - Also affected by HS/LB/vascular pathologies

The Religious Orders Study

- Began in 1993
- Enrolls older persons without dementia, annual F/U
- Older nuns, priests, and brothers without known dementia from across the U.S.
- All agreed to annual cognitive and motor testing, including a modified UPDRS
- All agreed to brain donation at the time of death
- ~
  - >90% follow-up rates
  - About 94% autopsy rate > 660 autopsies

The Rush Memory and Aging Project

… because memories should last a lifetime

- Community based study with similar methodologies but lay population more reflective of general population - began in 1997
- Residents from about 40 retirement communities and senior housing from across the Chicago area
- All agreed to annual cognitive/motor testing, blood draws
- All agreed to donate brain, spinal cord, muscle, nerve at the time of death
  F/U rates over 90%
- *Autopsy Rates 80%*
- *>650 autopsies*

- **Overall over 3160 enrolled/1520 died/1313 autopsies**

- **Annual visits: Interviews, Scales for depression, diet, decision making etc., Medical histories, Neurologic Exams, Neuropsych testing, Annual Clinical diagnoses of AD and other dementias (and final dx)**

- **Clinical testing for cognition**

  Episodic Memory: immediate and delayed recall Story A, WMS-R; immediate and delayed recall East Boston Story; Word List Memory, Recall and Recognition

  Semantic Memory: Verbal Fluency; Boston Naming; Vocabulary Test; National Adult Reading Test

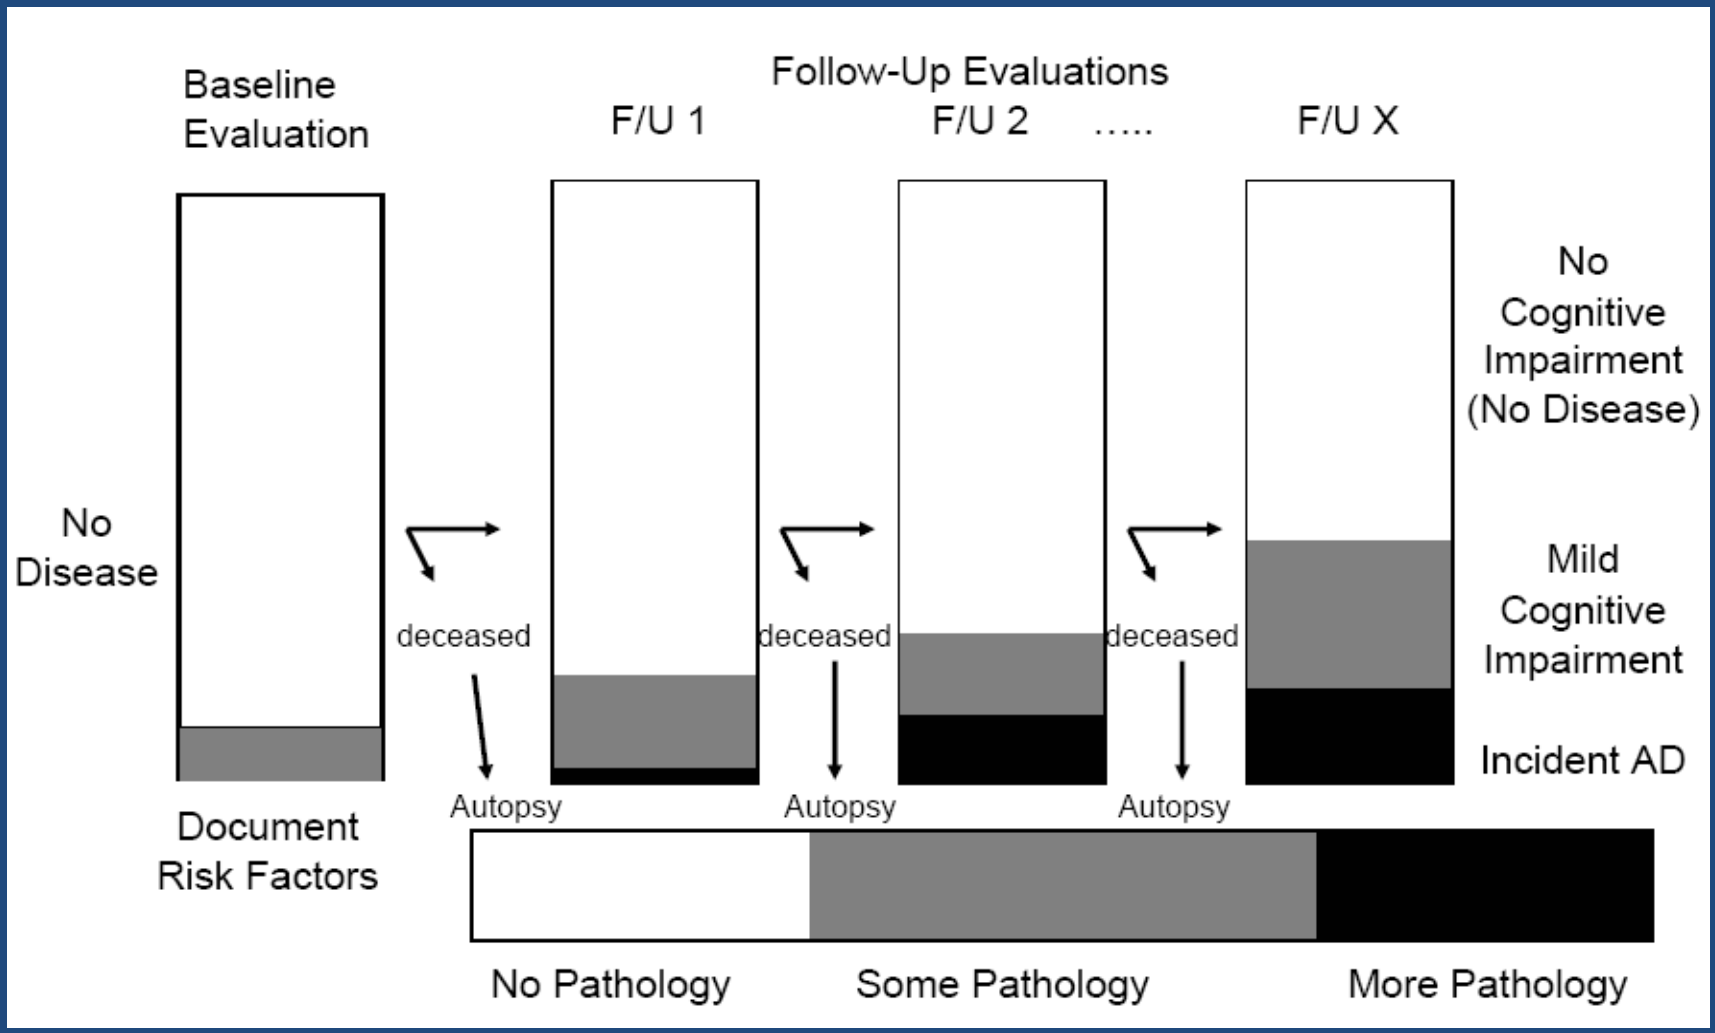
  Working Memory: Digit Span forward/backward; Digit Ordering; Alpha Span

  Perceptual Speed: Symbol Digit Modalities Test; Number Comparison

  Visuospatial Ability: Line Orientation; Progressive Matrices

Grouped to form a measure of overall cognitive function (global cognitive score)

The Rush Memory and Aging Project: Study Design and Baseline Characteristics of the Study Cohort



Bennett DA, et al. *Neuroepidemiology.* 2005;25:163–175.

Brain autopsies and AD Neuropathology

- Hemispheres cut into 1 cm slabs using a Plexiglas jig.
- Slabs from 1 hemisphere imaged, then fixed – other frozen

- Paraformaldehyde-fixed/paraffin-embedded/6µm sections

- **Pathologic Dx of AD** – using Bielschowsky/frontal, temporal, parietal, entorhinal, and hippocampal cx –

- Path diagnosis of AD
  - Modified NIA – Reagan (CERAD and Braak)
  - New NIA-AA criteria

- **Summary measure of AD pathology** using NP, DP, NFT counts from 5 regions and converting into standardized score

- Molecularly specific amyloid load and tau tangle densities also performed

Important notes about AD pathology

1. Moderately to strongly related to cognition/dementia; about 87% of those with clinical dx of AD dementia have dx confirmed by pathology

2. Inter-individual variation in the expression of AD pathology

3. Normal Aging

   - 1/3 have sufficient path for pathologic dx of AD
   - More subjective memory complaints and/or lower episodic memory than persons without the path diagnosis of AD

4. Mild Cognitive Impairment

   - AD pathology is intermediate between normals and demented
   - About ½ with sufficient pathology for a dx of AD but ~ 1/3 having no neocortical neuritic plaques; ~ 20% with Braak 1/2.

Neural Reserve

- 1/3 of older persons have sufficient AD pathology in brain to fulfill criteria for pathologic diagnosis of AD

- Those factors related to “reserve”
  - Education and Cognitive activities
  - Social, physical activity
  - Depression
  - Well-being/purpose in life
  - Diet
  - Genetic factors

  - Other age-related pathologies in the brain

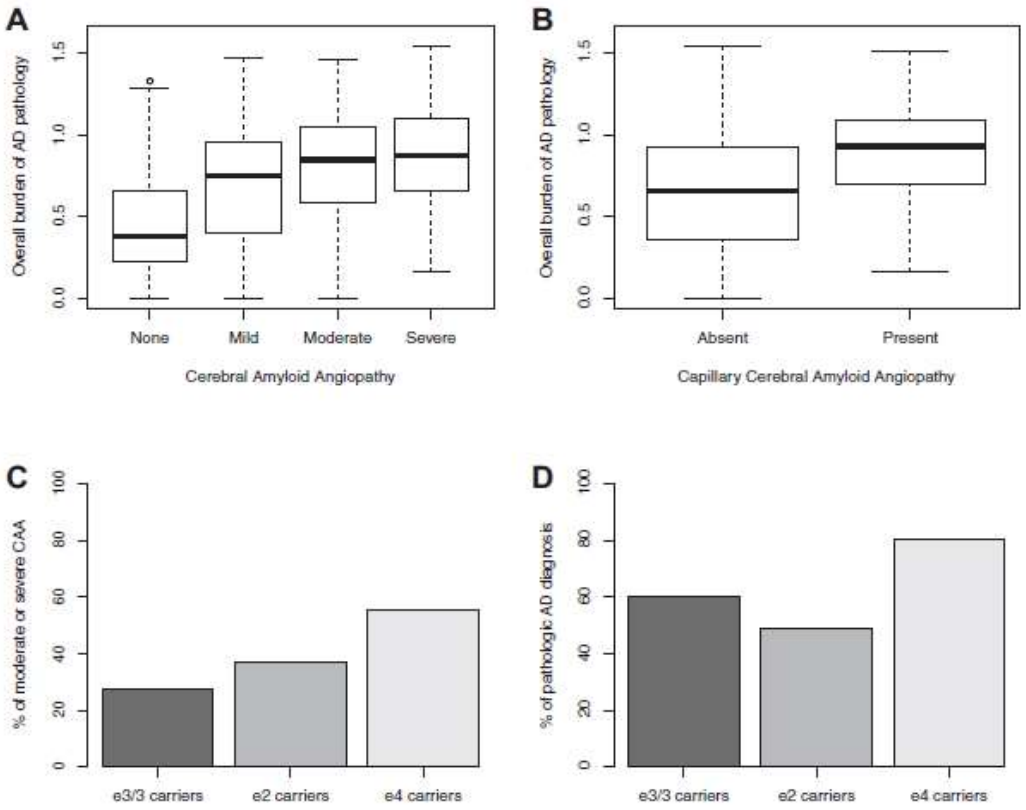

Fig. 2. Relationship of AD pathology, CAA, and *APOE* genotypes. (A and B) Distribution of the composite measure of AD pathology by CAA. The association of CAA with more burden of AD pathology is evident. (C) The percentages of moderate to severe CAA by *APOE* genotypes. The figure illustrates isoform-dependent pattern of *APOE* (i.e., ε4 > ε2 > ε3) in relation to CAA. (D) The percentages of pathologic AD diagnosis by *APOE* genotypes. Here, we observe a different pattern in relation to AD (i.e., ε4 > ε3 > ε2), as compared with CAA (C). Abbreviations: AD, Alzheimer's disease; APOE, apolipoprotein E; CAA, cerebral amyloid angiopathy.

Role for other pathologies in cognitive impairment in aging, MCI, dementia

- Lewy bodies - Neocortical LB increase odds of dementia and associated with all cognitive domains.
  - Limbic Lewy bodies related to impaired visuospatial skills

- TDP-43 – very common proteinopathy associated with aging, AD pathology, and HS; lowers episodic memory fxn and increases odds of dementia.

- Hippocampal sclerosis - very common in the oldest old and when associated with TDP-43 increases odds of MCI and dementia

- Mesial temporal lobe NFT and memory in late life – PART (primary age related tauopathy)

Original Investigation

TDP-43 Pathology, Cognitive Decline, and Dementia in Old Age

JAMA Neurol. 2013 Nov 1;70(11):1418-24.

Very common abnormal protein deposit in aging

Approximately 50% of cohort with TDP-43 pathology

Related to AD pathology and HS but also seen in those without AD or HS path dx.

Independently related to loss of episodic memory and increases odds of clinical AD

Effect size similar to tangles in mixed effect models on cog decline

ABSTRACT

Objective: To determine the independent association of the *TMEM106B* variants with transactive response DNA binding protein 43 (TDP-43) pathology in older persons without frontotemporal lobar degeneration (FTLD) and to explore functional pathways that link the risk variants to the pathology, including a *GRN* mRNA pathway.

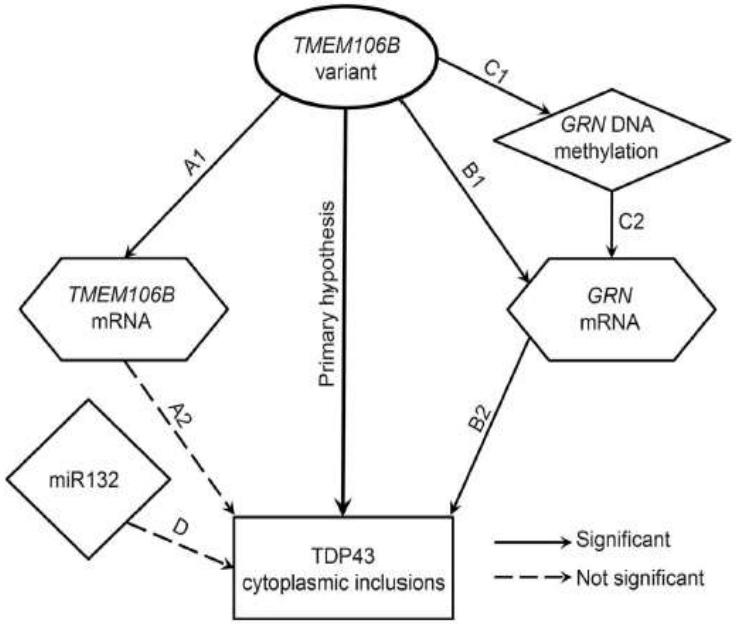
Methods: Data came from 544 autopsied participants without FTLD in 2 community-based studies of aging. Participants underwent uniform neuropathologic evaluations, including TDP-43 cytoplasmic inclusions. We examined the association of *TMEM106B* variants with a semiquantitative measure of TDP-43 pathology in a series of regression analysis. We explored potential pathways by leveraging genetic, brain DNA methylation, miRNA, and transcriptomic data collected from this same group of participants.

Results: TDP-43 pathology was identified in 51.7% of the participants. The index single-nucleotide polymorphism (SNP), rs1990622[A], was associated with more advanced TDP-43 pathology. Top hits from fine mapping of the locus were in linkage disequilibrium of the index SNP. The association remained significant after adjustment for other neuropathologies including Alzheimer disease and hippocampal sclerosis (odds ratio = 1.351, 95% confidence interval = 1.068–1.709, $p = 0.012$). *GRN* expression was upregulated in rs1990622[AA/AG] carriers, and was associated with more advanced TDP-43 pathology. The *TMEM106B* variants were associated with lower level of DNA methylation in an active enhancer in *GRN*.

Conclusions: Common variants in *TMEM106B* serve as a distinct risk factor for TDP-43 pathology in older persons without FTLD. The role of *GRN* expression and epigenetic mechanisms associating *TMEM106B* in the accumulation of TDP-43 in older persons require further study.

Neurology® 2015;84:927–934

Figure 1 Relationship and potential pathways linking *TMEM106B* variant and transactive response DNA binding protein 43 pathology



Each line in the figure represents a hypothesis tested in this study. The primary hypothesis is that transmembrane protein 106B (*TMEM106B*) variants are related to transactive response DNA binding protein 43 (TDP-43) pathology in aging after controlling for other common age-related pathologies. A (1 and 2) indicates the *TMEM106B* expression pathway; B (1 and 2) indicates granulin expression pathway; and C and D indicate potential epigenetic pathways. Solid lines indicate those relationships that were found to be significant. Dashed lines show relationships that did not reach significance (note miR132 pathway was not significant after controlling for other neurodegenerative pathologies).

Cairns · Dennis W. Dickson · Marla Gearing · Lea T. Grinberg · Patrick R. Hof · Bradley T. Hyman · Kurt Jellinger · Gregory A. Jicha · Gabor G. Kovacs · David S. Knopman · Julia Kofler · Walter A. Kukull · Ian R. Mackenzie · Eliezer Masliah · Ann McKee · Thomas J. Montine · Melissa E. Murray · Janna H. Neltner · Ismael Santa-Maria · William W. Seeley · Alberto Serrano-Pozo · Michael L. Shelanski · Thor Stein · Masaki Takao · Dietmar R. Thal · Jonathan B. Toledo · Juan C. Troncoso · Jean Paul Vonsattel · Charles L. White 3rd · Thomas Wisniewski · Randall L. Woltjer · Masahito Yamada · Peter T. Nelson

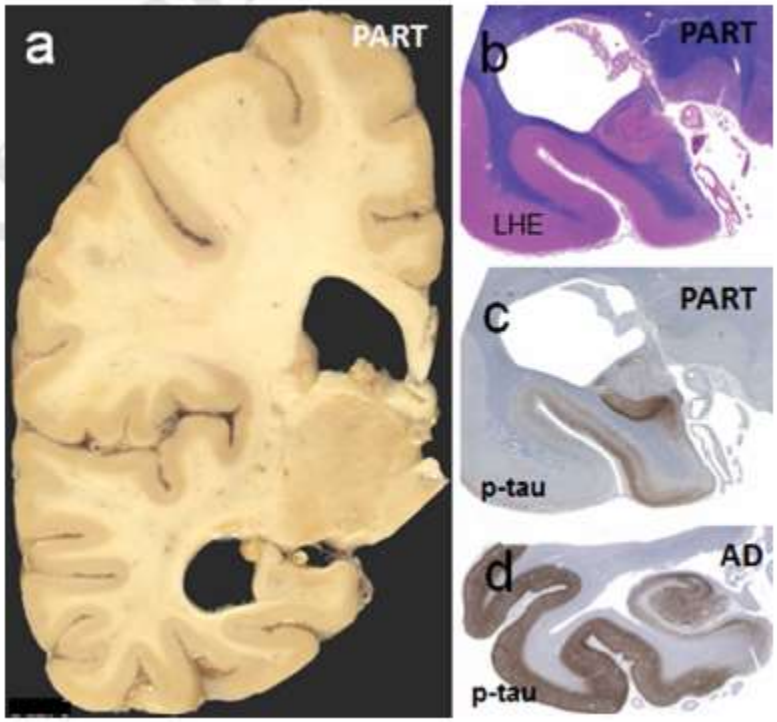

Table 2 Primary age-related tauopathy (PART): working classification

1. Requires

NFTs present with Braak stage ≤IV (usually III or lower)

2. Then subclassify as follows

Category	Thal Aβ Phase[a]	Other disease associated with NFT[b]
Definite	0	Absent
Possible	1–2	Absent

Examples

Primary age-related tauopathy (PART), Definite, Braak stage II

Primary age-related tauopathy (PART), Possible, Braak stage III, Thal Aβ phase 2

3. Ancillary studies (not required)

Immunohistochemistry: 3R and 4R tau-positive

Electron microscopy: paired helical filaments present

Genetics: absence of pathogenic FTLD-tau mutation

[a] See [116, 135]. Laboratories using the CERAD neuritic plaque density score [96, 97] may classify subjects with neuritic plaque frequency of "None" as "Definite" and "Sparse" as "Possible"

[b] For example, "progressive supranuclear palsy", "corticobasal degeneration", "Pick's disease", "frontotemporal lobar degeneration with *MAPT* mutation", and "chronic traumatic encephalopathy"

Implications

1. **Need to start thinking about sporadic AD dementia as a multifactorial syndrome**

2. **Epidemiologic studies:** One should be cautious making inferences – can not assume that risk factors for clinical AD are risks factors for AD pathology.

3. Episodic memory - primary domain affected by AD pathology, but also primary domain effected by TDP-43 pathology, HS, and PART, and also affected by vascular pathologies, and LB

4. Genetic factors may increase risk across diverse degenerative diseases.
